Nutritional status,

Uric acid,

Gout risk factor.

ABSTRACT

Gout or Gouty Arthritis is a degenerative disease. Gouty arthritis is a clinical syndrome that is caused by deposition of purine crystals in the tissues, due to levels of uric acid (hyperuricemia) in the extracellular fluid that passes through saturation. The etiology of gout arthritis included age, sex, history of medication, obesity, consumption of purine and alcohol. Aging is an important risk factor for men and women. This study uses an analytical-descriptive approach with cross-sectional design. This study was conducted to obtain a relationship between nutritional status and uric acid levels in the community in the area of Al-Hidayah Islamic Boarding School, Ngawi. This research was conducted in Majasem Village, Kendal District, Ngawi Regency, starting from 7 June - 31 August 2018. The results showed that there was a relationship between nutritional status and uric acid levels in the community in the area of Al-Hidayah Islamic Boarding School, Ngawi ($p=0,008$). Suggestions for further research are bivariate analysis based on gender, knowledge and attitude to response to diet so that other factors that influence can be seen clearly.

@2019 Medical and Health Science Journal. 10.33086/mhsj.v3i1.925

PENDAHULUAN

Life Expansion of Life Expectancy (UHH) is one indicator of the success of development in the health and welfare of the population. This has an impact on the increasing number of elderly people (elderly). Based on the 2013 United Nations report, UHH in 2013 was 71 years (with a percentage of the elderly population reaching 12%) (United Nations, 2013). The phenomenon of an increase in the number of elderly population is caused by a decrease in population fertility, improvement in health status due to technological advances and medical research, improvement in nutritional status which is marked by an increase in cases of obesity in elderly than underweight, to epidemiological transition from infectious diseases to degenerative diseases (Fatmah 2010).

Risk factors that are very closely related to this degenerative disease are lifestyle, including excess weight (obesity). National central obesity prevalence is 18.8%, where there is still a tendency to remain high when entering the elderly at 23.1% (age group 55-64), 18.9% (age group 65-74) and 15.8% (group 75 years and over) (WHO, 2012). The Indonesian Ministry of Health (2012) explains that excess nutrition in the elderly is usually associated with lifestyle and excessive consumption patterns from a young age even since children. In addition, the decreased metabolic process in the elderly if it is not balanced with an increase in physical activity or a decrease in the amount of food causes excess calories to be converted into fat causing obesity. This shows that overweight and obesity must also remain a concern

because it can spur the onset of degenerative diseases, especially gout.

Gout or Gouty Arthritis is a degenerative disease. Gouty arthritis is a clinical syndrome that is caused by deposition of purine crystals in tissues, due to levels of uric acid (hyperuricemia) in the extracellular fluid that passes through saturation (Tehupeiory, 2012). The etiology of gout arthritis included age, sex, history of medication, obesity, consumption of purine and alcohol. Aging is an important risk factor for men and women. This is likely due to many factors (Tehupeiory, 2012). Gout Arthritis (Gout) is a disease that is commonly found in men between 30-40 years of age, whereas in women aged 55-70 years, the incidence of women is rare except after menopause (Tjokropawiro, 2007 in Lumunon, 2015). In Indonesia, Gout arthritis ranks second after osteoarthritis (Dalimartha, 2008), the prevalence in Indonesia alone is estimated at 1.6-13.6 / 100,000 people, this prevalence increases with age (Tjokropawiro, 2007).

Kendal sub-district area is a sub-district located in Ngawi district, East Java. Kendal sub-district area is 84.56 km² with a population in 2016 of 44,376 people. Population of Kendal subdistrict based on age is controlled by the age range of 45-49 years, while the age above 60 years is 7,539 people (BPS Ngawi, 2017). With this data, the population of Kendal, Ngawi, is the age distribution of the population (old adults and elderly) is quite a lot so it is prone to degenerative diseases (gout).

Based on the description in the background of the problem above provides the basis for researchers to formulate the research questions as follows: What is the relationship between nutritional status and uric acid levels in the community in the Al-Hidayah Islamic Boarding School, Ngawi?

METHODS

This study uses an analytical-descriptive approach with cross-sectional design. This study was conducted to obtain a relationship between nutritional status and uric acid levels in the community in the area of Al-Hidayah Islamic Boarding School, Ngawi. This research was conducted in Majasem Village, Kendal District, Ngawi Regency, starting from 7 June - 31 August 2018. Sampling done by accidental sampling method. With this method the researcher will record every citizen who came / met when the research took place. If the inclusion criteria are included, the residents are entered into the study. The data will be processed with SPSS.17, univariate analysis to see the proportion between nutritional status and uric acid levels and presented in the frequency distribution table. Furthermore, the data was processed with bivariate regression correlation analysis to determine the relationship between nutritional status and uric acid levels and presented with tables.

RESULTS AND DISCUSSION

The study was conducted cross-sectionally at Al-Hidayah Islamic Boarding School, Kendal, Ngawi on June 24, 2018 at 09.00. Characteristics of respondents can be seen in table 4.1. Respondents who attended were mostly female, namely 64.4%. The average respondent present was the elderly (mean = 49) with a dominance of 42.2% of the age group 26-45. In the second place as many as 31.1% are the age group 56-65. The characteristics based on the latest education are dominated by elementary school graduates, namely 21 people with a percentage of 46.7%. In line with his latest education, almost 50% of livelihoods are farmers.

Table 4.1. Karakteristik Responden

No	Karakteristik Responden	Frekuensi (n=45)	Persentase
1	Jenis Kelamin		
	Perempuan	29	64.4
	Laki-laki	16	35.6
2	Usia		
	17-25	3	6.7
	26-45	19	42.2
	46-55	3	6.7
	56-65	14	31.1
	>65	6	13.3
3	Pendidikan Terakhir		
	S1	9	20
	S2	1	2.2
	SD	21	46.7
	SMA	3	6.7
	SMP	5	11.1
	Tidak Sekolah	6	13.3
4	Pekerjaan		
	Buruh	1	2.2
	Guru	7	15.6
	IRT	4	8.9
	Mahasiswa	1	2.2
	Pelajar	1	2.2
	Petani	22	48.9
	Swasta	6	13.3
	Wiraswasta	2	4.4
Tidak Bekerja	1	2.2	

In Univariate Nutritional Status analysis (table 4.2) only 35.6% had normal BMI. 55.6% have nutritional status above normal, 7 of them are overweight and 40 are obese. This proportion corresponds to the age distribution of many respondents from the 56-65 age group. According to WHO (2012), national obesity prevalence at the national level is 18.8%, where there is still a tendency to remain high when entering the elderly at 23.1% (age group 55-64), 18.9% (age group 65-74) and 15.8% (group 75 years and over).

Tabel 4.2 Univariat Satus Gizi berdasarkan Klasifikasi IMT

Klasifikasi IMT	Frekuensi	
	(n=45)	Persentase
1 Underweigh	4	8.9
2 Normal	16	35.6
3 Overweight	7	15.6
4 Obese	18	40.0
Total	45	100.0

Tabel 4.3 Univariat Kadar Asam Urat

	Kadar Asam Urat	Frekuensi (n=45)	Persenta se
1	Normal	36	80.0
2	Tinggi	9	20.0
	Total	45	100.0

More weight and obesity can trigger degenerative diseases, especially gout. However, in the univariate analysis of uric acid levels (table 4.3) it was seen at a glance that respondents who had high uric acid levels were only 9 people or 20% of the total while the other 80% were normal.

The results of research on nutritional status and uric acid levels of 45 respondents showed that respondents with normal nutritional status and underweight were safe from high levels of uric acid (table 4.4). While respondents with overweight nutritional status had 1 to 7 people, with high uric acid levels. This figure is increased in Obese IMT (> 25kg / m²) that is 8/18 or 44% have high uric acid levels. The data was reprocessed using the Chi-square calculation (table 4.5) and obtained a

significance of $p = 0.008$ which meant that there was a relationship between nutritional status and uric acid levels.

This has been conveyed in Budiono's research (2016) which states that the proportion of high levels of uric acid increases in respondents with high BMI. Likewise explained in the study by Lumunon (2015) in Manado, who took samples from elderly poly, that in the study there was a relationship between nutritional status and gout arthritis in the elderly in the work area of Manado Wawonasa Health Center. Factors that cause gouty arthritis proposed by Indriawan, 2009, one of them is diet, intake that enters the body also affects the level of uric acid in the blood. In this study also dominated by women (64.4%) so that a little more influence on the results of the study. The amount of food high in purine consumed will increase the risk of gout in elderly women who in fact have decreased immunity due to estrogen which is no longer produced and decreased metabolic power increases the risk of gout according to theory (Sylvia, 2006).

Tabel 4.4 Crosstabulation antara Klasifikasi IMT dan Kadar Asam Urat

		Kadar Asam Urat		
		Normal	Tinggi	Total
Klasifikasi IMT	Underweigh	4	0	4
	Normal	16	0	16
	Overweight	6	1	7
	Obese	10	8	18
	Total	36	9	45
